## 88 **1 Introduction**

89 This document defines the requirements for and scope of the WS-I Basic Security Profile. The  
90 document is aimed at Web Services architects and developers who are examining the security  
91 aspects of the Web Services they are designing/developing.

92 This document:

- 93 • Identifies security challenges. These are general security goals or features that inform the  
94 selection of specific security requirements in scenarios.
- 95 • Identifies the typical threats that prevent accomplishment of each challenge.
- 96 • Identifies the typical countermeasures (technologies and protocols) used to mitigate each  
97 threat.
- 98 • Documents potential usage scenarios and the security challenges and threats that might  
99 apply to each (derived from the templates found in the Supply Chain Management Use  
100 Cases and WS-I Usage Scenarios documents).

101 This document assumes that the reader has at least a basic background in security technologies  
102 such as SSL/TLS, XML encryption and digital signatures, and OASIS Web Services Security  
103 [WSS 1.0] Web Services Security: SOAP Message Security 1.0 (WS-Security 2004). It also  
104 assumes that the reader has a basic background in the message level technologies of SOAP.

105 .

## 106 2 Glossary

### 107 2.1 Basic Definitions

108 This section defines vocabulary that will be used to refer to the various entities and concepts in  
109 this document.

110 The following terms are used to describe certain entities.

- 111 • **Participant:** Any entity that plays some part in the scenarios. This is deliberately vague.  
112 No attempt is made to define entities or to characterize them. A participant might be a  
113 person, an institution, a computer, and a network or belong to some other category. Most  
114 obviously it includes the systems that exchange SOAP messages, but it also includes  
115 entities such as the original creator of content, or HTTP proxies that are not explicitly  
116 named in the scenarios.
- 117 • **SOAP Node:** [Copied with modification from [SOAP 1.1] The embodiment of the  
118 processing logic necessary to transmit, receive, process and/or relay a SOAP message,  
119 according to the set of conventions defined by SOAP 1.1 or SOAP 1.2. A SOAP node is  
120 responsible for enforcing the rules that govern the exchange of SOAP messages. It  
121 accesses the services provided by the underlying protocols through one or more SOAP  
122 bindings.

#### 123 2.1.1 Discussion

124 An alternative is to use “entity” as the most abstract term and reserve “participant” for the SOAP  
125 nodes that are parts of scenarios. However, “entity” sounds a bit stilted. Note that a SOAP node  
126 is a participant.

### 127 2.2 Messages

128 Communication channels are inevitably layered. When, as in this document, it is necessary to  
129 discuss the interaction between layers some care is required to distinguish between events and  
130 messages at one level from those that occur at a lower level. In general what appears to be an  
131 atomic action, such as message transmission, at one level will have a more complicated structure  
132 at a lower level.

133 We are primarily interested in transmission of SOAP messages and the participants in the  
134 transmission. However in some cases we are also interested in non-SOAP messages.

- 135 • **Message:** Protocol elements that are exchanged, usually over a network, to affect a Web  
136 service (i.e. SOAP/HTTP messages)
- 137 • **SOAP Message:** [Copied from [SOAP 1.2] The basic unit of communication between  
138 SOAP nodes.  
139  
140 Clarification: when using “SOAP with Attachments” [SwA] the attachments are  
141 considered part of the SOAP Message.
- 142 • **SOAP Layer:** The communication layer at which SOAP nodes reside.
- 143 • **HTTP Message:** The basic unit of HTTP communication, as defined in RFC 2616.
- 144 • **Transport Layer:** The communication layers below the SOAP layer.

- 145       • **SSL/TLS:** The communication layer below HTTP where security concerns are addressed  
146       See [RFC 2246]. There are technical differences between TLS and SSL, but these  
147       differences are not significant for this document. SSL/TLS refers to the profiled choice of  
148       SSL/TLS technology produced by the Basic Security Profile work group, and may thus be  
149       limited to versions of the technology as well as selected cipher suites and other profiling  
150       recommendations.
- 151       • **HTTPS:** The combination of HTTP with SSL/TLS.

### 152   **2.2.1 Discussion**

153   Normally HTTP and SSL/TLS would be considered separate layers. Consolidating them and  
154   lower layers compresses the stack. But it is convenient to treat HTTP, SSL/TLS and lower layers  
155   together.

## 156   **2.3 SOAP 1.2**

157   SOAP 1.2 defines the following terms:

- 158       • SOAP
- 159       • SOAP node
- 160       • SOAP role
- 161       • SOAP binding
- 162       • SOAP feature
- 163       • SOAP module
- 164       • SOAP message exchange pattern
- 165       • SOAP application
- 166       • SOAP message
- 167       • SOAP envelope
- 168       • SOAP header
- 169       • SOAP header block
- 170       • SOAP body
- 171       • SOAP fault
- 172       • SOAP sender
- 173       • SOAP receiver
- 174       • SOAP message path
- 175       • Initial SOAP sender
- 176       • SOAP intermediary
- 177       • Ultimate SOAP receiver.

178 **2.3.1 Discussion**

179 We adopt these terms with the understanding that we will apply them to SOAP 1.1 messages  
180 rather than SOAP 1.2 messages. We will not use any terms that refer specifically to SOAP 1.2  
181 features that are not present in SOAP 1.1

182 **2.4 Sending Messages**

183 The participants in a message event are referred to as

- 184 • **Sender:** [From [BP 1.0]] The software that generates a message according to the  
185 protocol(s) associated with it.
- 186 • **Receiver:** [From [BP 1.0]] The software that consumes a message according to the  
187 protocol(s) associated with it (e.g. SOAP processors).

188 In most contexts it is not necessary to distinguish the various layers in the communication,  
189 however when it is necessary to do so “sender” or “receiver” may be modified by the protocol  
190 involved, so that “SOAP sender” and “HTTP receiver” can be used.

191 **2.4.1 Discussion**

192 The use of “sender” and “receiver” is so natural that it would be hard to avoid them even if they  
193 weren’t part of the official glossary.

### 194 3 Security Challenges

195 This section identifies potential security challenges that scenarios may want to address. The  
196 following subsections characterize the identified security challenges with the following attributes:

- 197 • ID: A unique challenge identifier in the form C-*nn*.
- 198 • Definition(s): One or more relevant definitions related to this challenge taken from the  
199 Internet Security Glossary [RFC 2828]
- 200 • Explanation: Supporting web services contextual explanation and comments. With further  
201 review and development, some explanations may be suitable as input to a WS-I Glossary  
202 that lists security-specific terms.
- 203 • Candidate technology: Technology solutions that can be used to address security threats  
204 and risks associated with this challenge. The suitability of a candidate technology is  
205 discussed in the discussion of each specific scenario, taking into account considerations  
206 for that scenario.
- 207 • Threat association: A mapping of security threats associated with the challenge, with  
208 references to specific threats outlined in Section 4 and Section 7.2. Threats that are  
209 related specifically to the provided explanation are included within the threat association.  
210 Threats that relate to the underlying mechanisms that are needed to address the security  
211 challenge are not identified. For example the exchange of authentication data should  
212 leverage integrity and confidentiality mechanisms; however, specific integrity and  
213 confidentiality threats are not identified for authentication challenges.  
214 Threats enumerated in Section 4 are labeled T-XX. Those in Section 7.2 are considered  
215 “out of scope” and labeled T(OOS)-XX. “Out of Scope” means they are not addressed by  
216 any available candidate technology. There is no connection between the numbering of  
217 these two groups.

#### 218 3.1 C-01: Peer Identification and Authentication

##### 219 Definitions:

220 Peer entity authentication: The corroboration that a peer entity in an association is the one  
221 claimed.

222 Identification: An act or process that presents an identifier to a system so that the system can  
223 recognize a system entity<sup>1</sup> and distinguish it from other entities.

224 **Explanation:** Any relationship between entities can be considered an “association” for purposes  
225 of this definition. For example, it does not require that the two entities directly communicate with  
226 each other.

227 Although the term “authentication” is sometimes used to include both the presentation and the  
228 corroboration of an identifier this document uses “authentication” in the narrower sense defined  
229 here.

230 A participant may convey information to another participant to establish identity in conjunction  
231 with the use of techniques to corroborate that information. The two SOAP participants are not  
232 necessarily directly connected by a single hop, for example the participants might be the initial

---

<sup>1</sup> Note that *System Entity*, used throughout this document, refers to the definition in RFC 2828.

233 SOAP sender and a second SOAP intermediary. Depending on application requirements  
 234 (security policy) it may be reasonable to authenticate the sender, receiver or to use mutual  
 235 authentication.

236 **NOTE:**

237 It is important for a relying party to ensure the correctness of the identification associated with  
 238 authentication. For example, in using SSL/TLS a server may present an X.509 certificate to  
 239 associate identity information with a public key and use the corresponding private key to prove  
 240 possession of the private key. A relying party should not only rely on the authentication  
 241 technology, but should also ensure that the information associated with the authentication is  
 242 correct, thus authorizing further processing based on that information. This may include steps  
 243 such as ensuring that the HTTP request domain name corresponds to the server certificate name  
 244 and performing certificate validation. Such care is necessary in light of man-in-the-middle, DNS or  
 245 TCP/IP attacks (T-04) where authentication may work technically but does not corroborate the  
 246 correct party. Authorization is important but not addressed in this document.

247 **Candidate technology:**

- 248 • HTTPS with X.509 server authentication
- 249 • HTTP client authentication (Basic or Digest)
- 250 • HTTPS with X.509 mutual authentication of server and user agent
- 251 • OASIS SOAP Message Security

252 **Threat association:**

253 T-03, T-04, T-05, T-06, T-07, T(OOS)-01, T(OOS)-03, T(OOS)-04, T(OOS)-08, T(OOS)-13,  
 254 T(OOS)-14.

255 **3.2 C-02: Data Origin Identification and Authentication**

256 **Definitions:**

257 Data origin authentication: The corroboration that the source of data received is as claimed.

258 Identification: An act or process that presents an identifier to a system so that the system can  
 259 recognize a system entity and distinguish it from other entities.

260 **Explanation:** The provision and authentication of a declaration, carried in a web service message  
 261 that some entity vouches for certain parts of the message. Note that it is possible that more than  
 262 one entity might be involved in vouching for message parts. Also note that it is application-  
 263 dependent as to how it is determined who initially created the message, as the message  
 264 originator might be independent of, or hidden behind a vouching entity. This mechanism does not  
 265 provide for the authentication of the destination prior to transmission of application data.  
 266 However, the encryption of the data with a key only known to the legitimate destination can  
 267 effectively serve as an implicit form of destination authentication if that is required.

268 This of course does not prevent the impersonation of the legitimate destination for the purposes  
 269 of denial of service.

270 **Candidate technology:**

- 271 • OASIS SOAP Message Security
- 272 • MIME with XML Signature/XML Encryption

- 273       • XML Signature as used apart from OASIS SOAP Message Security and SOAP message  
274 exchanges, e.g. for identification and authentication of payloads

275       **Threat association:**

276       T-03, T-04, T-05, T-06, T-07, T(OOS)-01, T(OOS)-03, T(OOS)-04, T(OOS)-08), T(OOS)-13,  
277       T(OOS)-14.

278       **C-03: Data Integrity**

279       **Definition:** Data integrity: The property that data has not been changed, destroyed, or lost in an  
280 unauthorized or accidental manner (see [RFC 2828]).

281       **Explanation:** Data in a web services context is taken to mean a SOAP message or portions of a  
282 SOAP message, including one or more SOAP headers, a body, or attachment parts. Although  
283 data integrity is concerned with allowing a recipient of data to detect changes, whether accidental  
284 or malicious, data origin authentication mechanisms are required in conjunction with data integrity  
285 mechanisms in order to protect against active substitution and forgery attacks. When only  
286 providing integrity for portions of content, care must be taken to protect against subtle attacks,  
287 especially when a message is targeted at SOAP intermediaries as well as an ultimate receiver.

288       Note that the term “Integrity” is generally used differently in the field of information management  
289 to mean that the data is correct, proper, accurate, and consistent with other data or the real world.  
290 In this sense it usually implies that there are well-regulated procedures of creating, modifying and  
291 deleting the data. Here we are using “Integrity” in the security sense of not being altered without  
292 detection of such alteration even when under active attack.

293       **Threat association:** T-01. Additional threats associated with sub-categories of data integrity are  
294 listed below. Note that when used in conjunction with data origin authentication T-03, T-04 and T-  
295 05 are addressed.

296       **3.2.1 C-03A: Transport Data Integrity**

297       **Definition:**

298       Transport Data Integrity: Data integrity provided by the protocol layer that SOAP messages are  
299 bound to, e.g. HTTP secured by SSL/TLS (HTTPS).

300       **Explanation:** Transport integrity is applied to the entire SOAP message and may also include  
301 underlying protocol layers. For example, with HTTPS the HTTP message is also protected. Such  
302 transport layer security is “transient” in that the integrity is only effective while the transport  
303 session exists. Transport integrity is not appropriate for end-to-end security (from SOAP initiator  
304 to ultimate receiver) when SOAP intermediaries are present, since SOAP processing rules allow  
305 intermediaries to make changes to the SOAP message, and since transport protection is not in  
306 effect during intermediary processing.

307       **Candidate technology:**

- 308       • SSL/TLS with encryption enabled.

309       **Additional Threat Associations:** T-08, T(OOS)-10, T(OOS)-14.

310       **3.2.2 C-03B: SOAP Message Integrity**

311       **Definition:**

312       Soap Message Integrity: Data integrity applied at the SOAP Messaging layer in a manner that  
313 allows SOAP processing rules to be followed.

314 **Explanation:** SOAP message data integrity is for a web service message that may be processed  
 315 by SOAP intermediaries and may exist for extended periods of time at intermediary and/or  
 316 ultimate receiver SOAP nodes before being processed. The intention is to protect message data  
 317 even when not in transit, such as before processing is completed. An example is a SOAP  
 318 message waiting at a SOAP node for aggregation with other content yet to be processed.  
 319 Transport integrity is inappropriate for such cases since it terminates with the transport session.

320 SOAP message integrity should be applied to a SOAP message in a manner that enables  
 321 processing by SOAP intermediaries, which suggests that integrity protecting a combination of  
 322 SOAP header blocks the body and attachments is preferable to protecting the entire SOAP  
 323 envelope element or the entire SOAP header element. Protection may also include SOAP  
 324 attachments.

### 325 **Candidate technologies:**

- 326 • XML Signatures as profiled in the OASIS SOAP Message Security specification.  
 327 Note that keys may be conveyed out of band or with the message using a SOAP  
 328 Message Security token profile, including (but not limited to) Username tokens (for  
 329 derived keys) [UTP 1.0] Web Services Security Username Token Profile 1.0, X.509  
 330 [X509 1.0] Web Services Security X.509 Certificate Token Profile, Kerberos tokens,  
 331 SAML tokens [SAML 1.0] Web Services Security: SAML Token Profile, REL tokens  
 332 [REL 1.0] Web Services Security Rights Expression Language (REL) Token Profile,  
 333 or others.
- 334 • XML Signatures with MIME, not in the context of SOAP Message Security (out of  
 335 scope)

336 XML Signatures not in the context of SOAP Message Security headers can be used by  
 337 applications, but that use is not addressed in this document.

## 338 **3.3 C-04: Data Confidentiality**

339 **Definition:** Data confidentiality: The property that information is not made available or disclosed  
 340 to unauthorized individuals, entities, or processes [i.e. to any unauthorized system entity].

341 **Explanation:** The property that eavesdroppers or other unauthorized parties cannot view  
 342 confidential message content. Typically this is achieved with encryption. Note that confidentiality  
 343 is a distinct concept from privacy, so in the definition "disclosure" refers to the ability to view or  
 344 eavesdrop the information when transferred or processed. Confidentiality techniques may be  
 345 used as one aspect of maintaining privacy, however.

346 **Threat Associations:** T-02, T(OOS)-10, T(OOS)-14.

347 Disclosure related attacks as well as attacks that reduce the confidentiality strength (e.g. man-in-  
 348 the-middle SSL/TLS cipher suite attacks) are relevant.

### 349 **3.3.1 C-04A: Transport Data Confidentiality**

350 **Definition:** Data confidentiality provided by the protocol layers that SOAP messages are bound  
 351 to in a transport protocol stack specific manner. An example is HTTP secured by SSL/TLS  
 352 (HTTPS).

353 **Explanation:** Data confidentiality is applied to the entirety of the SOAP message as well as  
 354 possibly other protocol layers (e.g. HTTP when SSL/TLS is in use). With end-to-end  
 355 confidentiality between the initial SOAP sender and the ultimate receiver this prevents the use of  
 356 SOAP intermediaries.

357 **Candidate technology:**

- 358 • SSL/TLS with encryption enabled.

359 **Additional threat associations:**

360 none.

361 **3.3.2 C-04B: SOAP message confidentiality**

362 **Definition:** Data confidentiality applied at the SOAP messaging layer in a manner that allows  
363 SOAP processing rules to be followed.

364 **Explanation:** SOAP message confidentiality supports the confidentiality requirements unique to  
365 SOAP messaging, including:

- 366 1. SOAP intermediaries may be present and must be able to follow SOAP processing rules  
367 for the message, even when confidentiality has been applied.
- 368 2. Confidentiality may be applied to multiple portions of a SOAP message and be intended  
369 for different SOAP messaging participants.
- 370 3. A SOAP message (or portions) may retain confidentiality protection while not in transit.

371 This may include extended periods of time that the SOAP message is queued at an  
372 intermediary or ultimate receiver before being processed. An example is a SOAP  
373 message waiting at a SOAP node for aggregation with other content yet to be processed.

374 Transport confidentiality is generally inappropriate for these requirements since it terminates with  
375 the transport session.

376 In order for SOAP message confidentiality to be applied to a SOAP message in a manner that  
377 enables processing by SOAP intermediaries, a combination of SOAP header blocks, body blocks  
378 and attachments is appropriate, but the soap:Envelope, soap:Header and soap:Body elements  
379 must be visible to all parties and should not be encrypted. The SOAP message must also remain  
380 well-formed XML.

381 **Candidate technologies:**

- 382 • XML Encryption, as profiled by the OASIS SOAP Message Security specification.

383 **Additional threat associations:** none

384

385 **3.4 C-05: Message Uniqueness**

386 **Definition:** the ability to insure that a specific message is not resubmitted for processing.

387 **Explanation:** Attacker could resend all or selective parts of a message causing undesirable side  
388 effects. For example, an attacker sending the same valid message moving money from one bank  
389 account to another bank account. The original message request is valid, but not its replay.  
390 Additionally, sending the same valid message is frequently used in many denial-of-service  
391 attacks. While an application solution against replay attacks may utilize message ordering and  
392 reliable message delivery mechanisms, this security challenge makes no attempts to address  
393 these issues.

394 **Candidate technologies:**

- 395
- 396
- At the transport layer, using SSL/TLS between the node generating the request and the node insuring for downstream nodes that this is a unique request.
- 397
- At the message layer, the sending and receiving SOAP nodes must do a combination of different things. The sender must sign SOAP message header nonce, creation time[, expiration time] and optional user data. This user data may include critical transactional information and service identification elements. The transactional data protects the actual user request. The optional service identification elements protect the replay of the signature to another service that utilizes the same message data. The receiving node must verify the signature and check that the creation time is not stale. Lastly, it must compare the received nonce with a cache of previously received nonces. This cache of nonces must be maintained until the associated expiration time or the creation time plus a hard-coded delta has expired. Note: when multiple servers are performing this functionality, some mechanism must be implemented to create a functional global cache across all these systems.
- 398
- 399
- 400
- 401
- 402
- 403
- 404
- 405
- 406
- 407
- 408
- 409 **Threat association:** T-07, T-08, T-09, T(OOS)-14.

410 **4 Threats**

411 This section details a list of traditional security threats. Note that in many cases the threats  
 412 overlap. That is particular attacks may represent threats in several categories.

413

| ID   | Name                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| T-01 | Message Alteration      | The message information is altered by inserting, removing or otherwise modifying information created by the originator of the information and mistaken by the receiver as being the originator's intention. There is not necessarily a one to one correspondence between message information and the message bits due to canonicalization and related transformation mechanisms.                                                                                                                      |
| T-02 | Confidentiality         | Information within the message is viewable by unintended and unauthorized participants. (e.g. a credit card number is obtained).                                                                                                                                                                                                                                                                                                                                                                      |
| T-03 | Falsified Messages      | Fake messages are constructed and sent to a receiver who believes them to have come from a party other than the sender. For example, Alice sends a message to Bob. Mal copies some (or all of) it and uses that in a message sent to Bob who believes this new action was initiated by Alice. This overlaps with T-01. The principle is that there is generally little value to saying a message has not been modified since it was sent unless we know who sent it.                                  |
| T-04 | Man in the Middle       | A party poses as the other participant to the real sender and receiver in order to fool both participants (e.g. the attacker is able to downgrade the level of cryptography used to secure the message). The term "Man in the Middle" is applied to a wide variety of attacks that have little in common except for their topology. Potential designs have to be closely examined on a case-by-case basis for susceptibility to anything a third party might do.                                      |
| T-05 | Principal Spoofing      | A message is sent which appears to be from another principal (e.g. Alice sends a message which appears as though it is from Bob). This is a variation on T-03.                                                                                                                                                                                                                                                                                                                                        |
| T-06 | Forged claims           | A message is sent in which the security claims are forged in an effort to gain access to otherwise unauthorized information (e.g. A security token is used which wasn't really issued by the specified authority). The methods of attack and prevention here are essentially the same as T-01                                                                                                                                                                                                         |
| T-07 | Replay of Message Parts | A message is sent which includes portions of another message in an effort to gain access to otherwise unauthorized information or to cause the receiver to take some action(e.g. a security token from another message is added).Note that this is a variation on T-01. Like "Man in the Middle" this technique can be applied in a wide variety of situations. All designs must be carefully inspected from the perspective of what could an attacker do by replaying messages or parts of messages. |

| ID   | Name              | Description                                                                                                                                                                                          |
|------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| T-08 | Replay            | A whole message is resent by an attacker                                                                                                                                                             |
| T-09 | Denial of Service | Amplifier Attack: attacker does a small amount of work and forces system under attack to do a large amount of work. This is an important issue in design and perhaps merits profiling in some cases. |

## 427 **5 Security Solutions, Mechanisms and Countermeasures**

428 In this section, we provide a high-level description of security solutions, which are defined in  
429 terms of security layers that address the SOAP message security challenges in section 3. We  
430 then define the specific security mechanisms and associated countermeasures that are  
431 addressed by the Security Profiles.

432 Mechanisms to address security challenges may be applied at different communication layers  
433 and possibly in combination. The primary concerns of this document are the SOAP and transport  
434 layers. Within the transport layer the focus is primarily on HTTP and HTTPS. Combinations of  
435 security mechanisms in the layers may be applied to satisfy different security requirements.

436 SOAP layer mechanisms may be used to provide security for attachments.

437 This document focuses on scenarios for transport and SOAP layer security. Users may  
438 implement their own data (payload) layer security, but data layer security is not addressed  
439 explicitly in this document.

440 Transport and SOAP security layers can be configured to address a variety of security  
441 requirements. These variations are enumerated later in this section. We define abstract security  
442 functions that may be used to address the various security threats that we previously described in  
443 section 4.

### 444 **5.1 Transport Layer Security Descriptions**

445 The protocol layers that provide transport for the SOAP Messaging protocol (transport layer) may  
446 be used to provide security services to meet application or SOAP Messaging security  
447 requirements. This may be done in combination with SOAP message security mechanisms or  
448 independently. This section focuses on the transport mechanisms only. These mechanisms  
449 provide integrity and/or confidentiality for HTTP messages.

450 Because the only transport mechanism within the scope of this document is HTTP (optionally  
451 over SSL/TLS) we assume that each SOAP node has an associated HTTP node, which might be  
452 a part of the SOAP node or might be a distinct entity. We also assume that SOAP messages  
453 between nodes are carried on HTTP messages between their associated HTTP nodes.  
454 Communication between a SOAP node and its associated HTTP node is regarded as internal to a  
455 platform and we make no assumptions about its nature or the information transferred other than

- 456 • The SOAP message itself is communicated.
- 457 • When an HTTP request containing a SOAP message is sent over a connection that was  
458 established using some HTTP authentication mechanism, the HTTP server will  
459 communicate to its associated SOAP node the identity that was established by that  
460 authentication mechanism. We do not assume that it communicates any credential used  
461 to establish that identity.

462 Note in particular that we do not assume any communication between the associated HTTP and  
463 SOAP nodes with regards to the certificates used to establish a TLS/SSL connection.

464 In what follows when a word or phrase such as “N” refers to a specific SOAP node we use the  
465 notation “N-HTTP” to refer to its associated HTTP node.

### 466 5.1.1 Integrity

467 Integrity may be provided for an entire SOAP message using the transport layer. When SSL/TLS  
468 is used in conjunction with HTTP (HTTPS), the entire HTTP message, including the start-line  
469 (e.g. POST), HTTP headers, and body receives integrity protection. This SOAP message  
470 conveyed in the HTTP body is also protected. This integrity is only in effect for the duration of the  
471 HTTP session and provides no protection for SOAP messages once received (and possibly  
472 queued by the web service consumer or provider). Note that integrity is provided for the entire  
473 SOAP message – partial integrity is not possible with this mechanism. This mechanism is not  
474 suitable for end-end SOAP message integrity in the presence of SOAP intermediaries.

475

476 The basic operation of this mechanism is as follows:

- 477 1. SOAP node A's associated HTTP node initiates an HTTPS connection to another SOAP  
478 node B's associated HTTP node.
- 479 2. SSL/TLS session is established, starting integrity protection
- 480 3. SOAP messages are conveyed from A to B, potentially a SOAP message or fault is  
481 conveyed in the HTTP response
- 482 4. HTTP and SSL/TLS session is terminated, ending integrity protection

483

484 Note that the quality of SSL/TLS integrity protection depends on an adequate SSL/TLS cipher  
485 suite and key length being selected. Care must be taken in selection of cipher suites and key  
486 lengths to prevent downgrade attacks. Options with inadequate security should not be offered  
487 even if they are supported in the code. Determination of adequate levels of security is, of course,  
488 a matter of individual policy. However, the Profile will make some recommendations where  
489 appropriate.

490

### 491 5.1.2 Confidentiality

492 Confidentiality may be provided for an entire SOAP message using the transport layer. When  
493 SSL/TLS is used in conjunction with HTTP (HTTPS), the entire HTTP message including HTTP  
494 headers is protected as well. This confidentiality is only in effect for the duration of the HTTP  
495 session and provides no protection for SOAP messages once received (and possibly queued by  
496 the web service consumer or requestor). Confidentiality is applied to the entire SOAP message;  
497 partial confidentiality is not possible, making this unsuitable for SOAP messages to be conveyed  
498 through SOAP topologies involving SOAP intermediaries.

499 The basic operation of this mechanism is the same as that using transport layer to provide  
500 integrity. [Section 5.1.1

501 Note that the presence and quality of SSL/TLS integrity protection depends on an adequate  
502 SSL/TLS cipher suite and key length being selected. Care must be taken in selection of cipher  
503 suites and key lengths to prevent downgrade attacks. Options with inadequate security should not  
504 be offered even if they are supported in the code.

505

### 506 5.1.3 Authentication by HTTP Service

507 A SOAP node A whose associated HTTP node initiates a connection from SOAP node B's  
 508 associated HTTP node may authenticate B using transport layer mechanisms such as SSL/TLS.  
 509 In the SSL/TLS case the authentication consists of a server X.509 certificate combined with a  
 510 proof of private key possession as part of the SSL/TLS protocol. In addition, some clients may  
 511 perform additional checks such as comparing the service URL domain name against the  
 512 certificate distinguished name, for example, to attempt to detect certificate substitution attacks.  
 513 Finally, relying parties should perform a certificate validation check to ensure that the certificate  
 514 was not revoked, either due to private key compromise or other reasons before relying on the  
 515 validity of the authentication information.

516 The basic operation of the mechanism is as follows:

- 517 1. HTTP node associated with A initiates HTTPS connection to HTTP node associated  
 518 with B.
- 519 2. As part of establishing SSL/TLS session, B's HTTP node authenticates to A's HTTP  
 520 node
- 521 3. SOAP messages are conveyed from A to B, potentially SOAP message or fault is  
 522 conveyed in HTTP response
- 523 4. HTTP and SSL/TLS session is terminated

524 Note that the authentication is for the session and that by default there is no lasting record or  
 525 association of the authentication action with the SOAP message.

### 526 5.1.4 Authentication by HTTP User Agent

527 A SOAP node A whose associated HTTP node initiates a connection to SOAP node B's  
 528 associated HTTP node may authenticate to SOAP node B. If B's HTTP node also authenticates  
 529 to A's HTTP node it is said to be mutual authentication.

530 Note that a web service provider might authenticate at the transport layer and the web service  
 531 consumer at the SOAP messaging layer, depending on the desired authentication properties.

532 An HTTP user agent authentication may be:

- 533 • HTTPS client X.509 certificate authentication,
- 534 • HTTP basic or digest authentication with HTTPS confidentiality
- 535 • HTTP basic or digest authentication without HTTPS confidentiality

#### 536 5.1.4.1 HTTPS X.509 client Authentication

- 537 1. A's HTTP node initiates HTTPS connection to B's HTTP node
- 538 2. As part of establishing SSL/TLS session, web service consumer authenticates to provider  
 539 using X.509 client certificate with private key proof of possession as part of SSL/TLS  
 540 protocol
- 541 3. Once HTTPS session is established A sends SOAP messages and the HTTP response  
 542 may convey a SOAP message or Fault.
- 543 4. HTTPS session is closed, ending authenticated transfer

544

545 5.1.4.2 HTTP Basic or Digest authentication with HTTPS Confidentiality

546 HTTP Basic and Digest authentication mechanisms are outlined in [RFC 2617],

547 1. A-HTTP node initiates HTTPS connection to B-HTTP node with HTTPS confidentiality  
548 (requires appropriate cipher suite etc)

549 2. HTTP Basic or Digest authentication performed as part of SOAP message request POST

550 HTTPS session is closed

551 Note that B-HTTP must request authentication explicitly. The SOAP message may be POSTed  
552 twice – once in the original POST that results in an HTTP response requesting authentication and  
553 then in the request that conveys the authentication information in the header. This could be an  
554 issue for large SOAP messages.

555 Adequate protection against replay attacks is required with HTTP authentication and POSTs as  
556 noted by RFC 2617. HTTPS confidentiality requires appropriate cipher suites and protection  
557 against downgrade attacks.

558 Using HTTP with Digest authentication provides no real benefits in terms of authentication over  
559 Basic authentication, although with the proper cipher suites it can provide integrity.

560 5.1.4.3 HTTP Basic or Digest Authentication in the clear

561 HTTP Basic or Digest authentication performed as part of HTTP session that includes SOAP  
562 message request POST.

563 Despite the risk of insider attack (most attacks are insider attacks) HTTP authentication without  
564 HTTPS may be appropriate within an enterprise or other secured environments. Protection  
565 against replay attacks is required as noted by RFC 2617.

566 **5.1.5 Attributes**

567 Attributes may be conveyed in HTTP header fields [RFC 2616]. This may require integrity and/or  
568 confidentiality protection using HTTPS, depending on application requirements.

569 Attributes may also be conveyed in the HTTPS client X.509v3 certificate through the use of  
570 certificate extensions, although this may not be interoperable. See PKIX RFC 3280.

571 **5.1.6 Combinations**

572 The preceding transport layer security mechanisms may be combined with each other as needed.  
573 The following table attempts to identify the combinations that we believe are significant with a  
574 unique tag that we will use in later sections.

575

| Challenge Supported              | Transport Layer Technologies being Utilized     | Tag <sup>2</sup> | Comment                                                                                                              |
|----------------------------------|-------------------------------------------------|------------------|----------------------------------------------------------------------------------------------------------------------|
| Integrity                        | SSL/TLS                                         | BISP1            | Assuming that cipher suites NULL-SHA or NULL-MD5 are not being supported because these suites do support encryption. |
| Confidentiality                  | SSL/TLS                                         |                  |                                                                                                                      |
| Provider (server) Authentication | SSL/TLS                                         |                  |                                                                                                                      |
| Consumer (client) Authentication | SSL/TLS <sup>3</sup> with client authentication | BC1              | Assume X.509 certificates being used to identify consumer and provider with mapping to trusted root CA.              |
|                                  | HTTP Basic                                      | BC2              |                                                                                                                      |
|                                  | HTTP Digest                                     | BC3              |                                                                                                                      |
|                                  | HTTP Attributes                                 | BC4              |                                                                                                                      |
|                                  | SSL/TLS                                         | HTTP Basic       |                                                                                                                      |
|                                  | HTTP Digest                                     |                  |                                                                                                                      |

576

**Table 2: Transport Level Security Options**

577 The intention is for an application developer to select one or more solutions that address the  
 578 relevant security challenges. For example, if consumer authentication is required then any one of  
 579 the BCx solutions would meet this need.

580 As indicated, a single solution may meet multiple security challenges. For example, assuming  
 581 cipher suites NULL-SHA or NULL-MD5 are not supported, using SSL/TLS will ensure transport  
 582 layer integrity, confidentiality and provider authentication.

583 **5.2 SOAP Message Layer Security Descriptions**

584 Security services may be provided at the SOAP Messaging protocol layer using the SOAP  
 585 Message Security specification from the OASIS SOAP Message Security technical committee in  
 586 conjunction with token specifications developed in that committee. These security mechanisms  
 587 may be combined with the transport layer security mechanisms discussed above.

---

2 The tag naming convention consists of three parts. The first character is a “B” in the first character to identify that this is a binding level solution. (Note: “T” was not used because of possible confusion with “T” used by Threat tags.) The next 1 to 3 letters identify the transport challenge: “I” for Integrity, “S” for confidentiality (Secret), “P” for Provider authentication, and “C” for Consumer authentication. The last component is a number identifying the solution instance.

3 Note: user can support NULL-SHA or NULL-MD5 cipher suites for this usage.

### 588 5.2.1 Integrity

589 Integrity may be provided to a portion or combination of SOAP message content using XML  
590 Digital Signature as outlined in the SOAP Message Security specification. Such integrity has the  
591 advantage that it remains with the SOAP message beyond an HTTPS session, suitable for  
592 providing end-end integrity despite SOAP intermediaries, when used properly.

- 593 1. SOAP Sender (either initial SOAP Sender or SOAP Intermediary) protects integrity of  
594 some portion or combination of SOAP body, attachments and header blocks using an  
595 XML Digital Signature placed in a wsse:Security header block targeted at the SOAP  
596 receiver relying on integrity. SOAP Sender may also convey key information using  
597 security tokens in the message header enabling relying party to verify signatures. Note  
598 that in some cases integrity may be relied upon by more than one SOAP receiver. In  
599 case portions of the message are persisted with their signature integrity may be relied  
600 upon by participants besides SOAP receivers.
- 601 2. Message is sent, potentially through one or more SOAP intermediaries. SOAP role  
602 associated with SOAP security header for integrity protection determines relying party.  
603 Depending on how SOAP role is defined integrity may be verified by multiple SOAP  
604 receivers.

### 605 5.2.2 Confidentiality

606 Confidentiality may be provided to portions or some number of SOAP Message content using  
607 XML Encryption as outlined in the SOAP Message Security specification. Note that encryption  
608 must not be applied so that SOAP message processing cannot be performed. SOAP message  
609 confidentiality protection has the advantage that it remains with the SOAP message beyond an  
610 HTTPS session, and is suitable for providing end-end confidentiality despite SOAP intermediaries  
611 when used properly.

- 612 1. SOAP Sender (either initial SOAP Sender or SOAP Intermediary) protects confidentiality  
613 of some combination of SOAP body, or header blocks or portions using XML Encryption  
614 as outlined in SOAP Message Security. Sender may also convey key information using  
615 security tokens in the message header.
- 616 2. Message is sent, potentially through one or more SOAP intermediaries. Depending on  
617 processing roles and rules, confidentiality may be applicable for one or more SOAP  
618 receivers. Special consideration must be given to either the replacement of encrypted  
619 data with clear data by intermediaries since this modification could break any signatures  
620 that referenced the encrypted data.

621

### 622 5.2.3 SOAP Sender Authentication

623 A SOAP Sender (either an initial SOAP sender or a SOAP intermediary) may provide  
624 authentication for one or more SOAP receivers by including one or more appropriate SOAP  
625 Message security tokens in security headers targeted at the receiver roles may be used in  
626 combination with XML Signatures as profiled by SOAP Message Security to provide confirmation  
627 of the token claims and to bind the claims to the message.

628 Note that in a SOAP message from a web service consumer to a web service provider, SOAP  
629 sender authentication authenticates the consumer. In a SOAP message from a web service  
630 provider to a web service consumer (such as conveyed in an HTTP response in a request-  
631 response MEP) then SOAP sender authentication authenticates the provider to the consumer.  
632 SOAP receiver authentication as such does not make sense given a one-way message.

633 **5.2.4 Attributes**

634 Attributes may be conveyed in application specific SOAP Message Security XML or Binary  
 635 security tokens (SOAP Message Security extension points), or SOAP Message Security SAML  
 636 Tokens conveying attribute assertions to give two examples.

637 **5.2.5 Message Uniqueness**

638 This functionality is build upon the message integrity mechanisms, digital signatures, referred to  
 639 in Section 5.2.1 being applied to several fields with special semantics and a number of things  
 640 outside the actual message exchange. Depending upon the type of security token being utilized  
 641 by the application to authenticate the sender, different elements in the message may be utilized.  
 642 All the solutions are built upon the following key types of information being present in the sender  
 643 message:

644 Unique message identifier: this element is used to uniquely identify the message. No two  
 645 messages should ever have this value. While this data could be  
 646 consequently assigned sequence numbers or non-random data, experience  
 647 has shown that such practices allow for session hijacking unless the  
 648 associated authentication mechanisms are very strong. Using true random  
 649 values for the message identifier is best practice because an attacker can not  
 650 effectively guess what message identifier someone is using or may use.  
 651 [Some form of this element must be present in any solution]

652 Timestamp: a time that bounds the associated message identifier lifetime. Without this  
 653 value, the consuming entity would potentially have to maintain data to track  
 654 all message identifiers that it has ever processed. For some restrictive  
 655 environments, e.g., single source, this timestamp can be used for the unique  
 656 message identifier. In general, this is not true. The bigger issue with the  
 657 timestamp is that the sending and receiving systems must be loosely time  
 658 synchronized so that the receiving system does not have to maintain an  
 659 ever-increasing database of processed message identifiers. With the  
 660 availability of clock synchronization protocols and the receiver ability to  
 661 control the size of the time window, applications can control the degree of  
 662 time synchronization needed. While careful date/time set up could work if an  
 663 application supports a large time window, e.g., 5-10 minutes, in general  
 664 some form of clock synchronization is really required for effective operation.  
 665 [Some form of this element must be present in any solution]

666 Optional Application Restrictions: These elements allow an application to prevent the  
 667 replay of the preceding elements to different receiving systems. For example,  
 668 to prevent a valid message identifier and application message data from  
 669 being sent to a different receiving system and being processed, the domain  
 670 of the target service that this request is intended for could be included within  
 671 the data to be signed. [This is application dependent data with associate  
 672 application semantic checking.]

673 Of the different types of security tokens that our profile is committed to address, i.e., X.509  
 674 certificates, username, Kerberos, SAML and REL, only username tokens currently have elements  
 675 defined that map to the unique message identifier and timestamp element just described.

676 *As will become very apparent, no security token profile and other standards will deliver a fully*  
 677 *operational solution to the message uniqueness challenge at the SOAP message layer.*

## 678 5.2.5.1 Username Token

679 In particular, the username token profile defines the following elements that the sending system  
680 must populate when building a message uniqueness solution:

681 Nonce: a random value that the sender generates and uses as the unique message  
682 identifier. [The nonce is a recommended element in OASIS Username Token  
683 Profile that can be overloaded to serve as the unique message identifier.  
684 When used for replay prevention, this element must be present. When used  
685 for this purpose, it must be large enough to ensure that multiple simultaneous  
686 requesters do not generate the same nonce value causing a false positive.]

687 Creation Time: the time that the associated nonce was created. [The creation time is a  
688 recommended element in OASIS Username Token Profile that can be  
689 overloaded to serve as the timestamp. When used for replay prevention, this  
690 element or expiration time element must be present.]

691 Expiration Time: the time when the associated nonce is no longer valid to be used. [The  
692 expiration time is an optional element in OASIS Username Token Profile that  
693 can be overloaded to serve as the timestamp. If not present, then the  
694 receiving system must add an internally configured delta time to the creation  
695 time element.]

696 Additionally, the preceding required and optional data along with the username must be signed by  
697 the sender so that the receiving system can ensure that none of the preceding elements has  
698 been modified by an attacker. This comes with the unstated assumption that the signing key  
699 (some function of the associated password) is known only to the sender and receiver as either an  
700 out-of-band shared secret or encrypted. Otherwise, the receiver can not authenticate the sender  
701 is who then say they are.

702 On the receiving system, the receiver must perform the following actions:

- 703 1. Verifying the signature containing the nonce, timestamps and optional restriction data.  
704 Note: this check is completely independent from any other integrity checking that the  
705 sender/receiver may be performing.
- 706 2. Check that the expiration time (or creation time + maximum delta) is less than the current  
707 time.
- 708 3. Looking up the nonce value in a nonce cache. If the nonce value is already present, then  
709 fail the request. If the nonce value is not present, then add the nonce and expiration time  
710 values to the cache. If multiple receiving systems are concurrently active, then the nonce  
711 cache must be across all servers in the pool. Independently, the nonce cache should  
712 automatically delete expired nonces. Our intention is to describe the abstract processing  
713 that the receiver is performing, not the implementation specifics. [This functionality is  
714 application specific because no existing standard/protocol covers this functionality.]
- 715 4. Perform any application specific restriction checks, e.g., checking target domain. [This  
716 functionality is application specific because no existing standard/protocol covers this  
717 functionality.]

## 718 5.2.5.2 X.509 Certificate, Kerberos, SAML and REL Tokens

719 The OASIS X.509 Certificate, SAML and REL Token Profiles, as well as the upcoming OASIS  
720 Kerberos Token Profile, do not have the required elements that can act as a message identifier.  
721 This requires the application developer to define proprietary elements to address these needs  
722 outside of the scope of these token profiles.

723 5.2.5.3 Other Token Types

724 There are other token types being worked on that contain nonce and timestamp elements.  
725 However, their detail characteristics may prohibit them for being used to prevent replay attacks.

726 **5.2.6 Combinations**

727 The preceding message layer security mechanisms may be combined with each other as  
728 needed. The following table attempts to identify the combinations that we believe are significant  
729 with a unique tag that we will use in later sections.

730

| Challenge Supported        | Message Layer Technologies being Utilized |                              | Tag <sup>4</sup> | Comment                                                                                                                                      |
|----------------------------|-------------------------------------------|------------------------------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| Integrity                  | XML Digital Signature                     |                              | SI1              |                                                                                                                                              |
| Confidentiality            | XML Encryption                            |                              | SC1              |                                                                                                                                              |
| SOAP Sender Authentication | XML Encryption                            | username & [password digest] | SA1              | Without the ability to encrypt password/digest, sender open to man-in-middle stealing password/digest and reusing it.<br><br>SOAP Attributes |
|                            |                                           | username & [password digest] | SA2              |                                                                                                                                              |
|                            |                                           | X.509 Certificate            | SA3              |                                                                                                                                              |
|                            |                                           | Kerberos Token <sup>5</sup>  | SA4              |                                                                                                                                              |
|                            |                                           | SAML Token                   | SA5              |                                                                                                                                              |
|                            |                                           | REL Token                    | SA6              |                                                                                                                                              |

731

**Table 3: SOAP Message Level Security Options**

732

The intention is for an application developer to select one or more solutions that address the relevant security challenges. For example, if SOAP sender authentication is required then any one of the Sx solutions would meet this need.

733

734

735

Missing from this table is SOAP receiver authentication. Receiver message layer authentication can only be supported by a response message in which the role of the sender and receiver has been exchanged, i.e., the sender is the provider.

736

737

738

### 5.3 Combining Transport Layer and SOAP Message Layer Mechanisms

739

As noted above security services may be provided at either or both the transport layer and the SOAP message layer. The choice often depends on application requirements, based on answers to questions such as:

740

741

742

1. Is it necessary to apply integrity and/or confidentiality at a granularity other than the entire SOAP message? This is usually true when SOAP intermediary processing is expected.

743

744

2. Does the protection need to exist beyond the transport session, protecting SOAP messages when queued at a SOAP node for example?

745

4

The tag naming convention consists of three parts. The first character is a “S” in the first character to identify that this is a SOAP message level solution. The next letter identifies the type of SOAP message level challenge: “I” for Integrity, “C” for Confidentiality, “A” for SOAP sender Authentication. The last component is a number identifying the solution instance.

5

Kerberos tokens are part of our charter candidate technologies. However, usage of this technology in this profile will be deferred until OASIS TC delivers this core specification. Note also that as other types of security tokens are added to our list of charter technologies, they will be added to these security profiles.

746 3. Is there a need to save evidence such as authentication assertions for subsequent  
747 dispute resolution?

748 4. Is there a need for transport layer protocol independence?

749 5. How important is interoperability of attribute information?

750 Special cases are noted in the sections above where additional mechanisms are required to  
751 ensure security. In general, minimizing combinations while following recommended security  
752 practices for the security technologies should reduce risks.

## 753 **5.4 Transport and Message Layer Security Combinations**

754 This section describes a selected subset of common security scenarios and identifies potential  
755 solutions for various security requirements. The security requirements vary from simple to  
756 complex depending upon the mechanisms selected and the underlying need. This approach  
757 allows the users to select a specific security scenario and implementation mechanisms that best  
758 meet their needs.

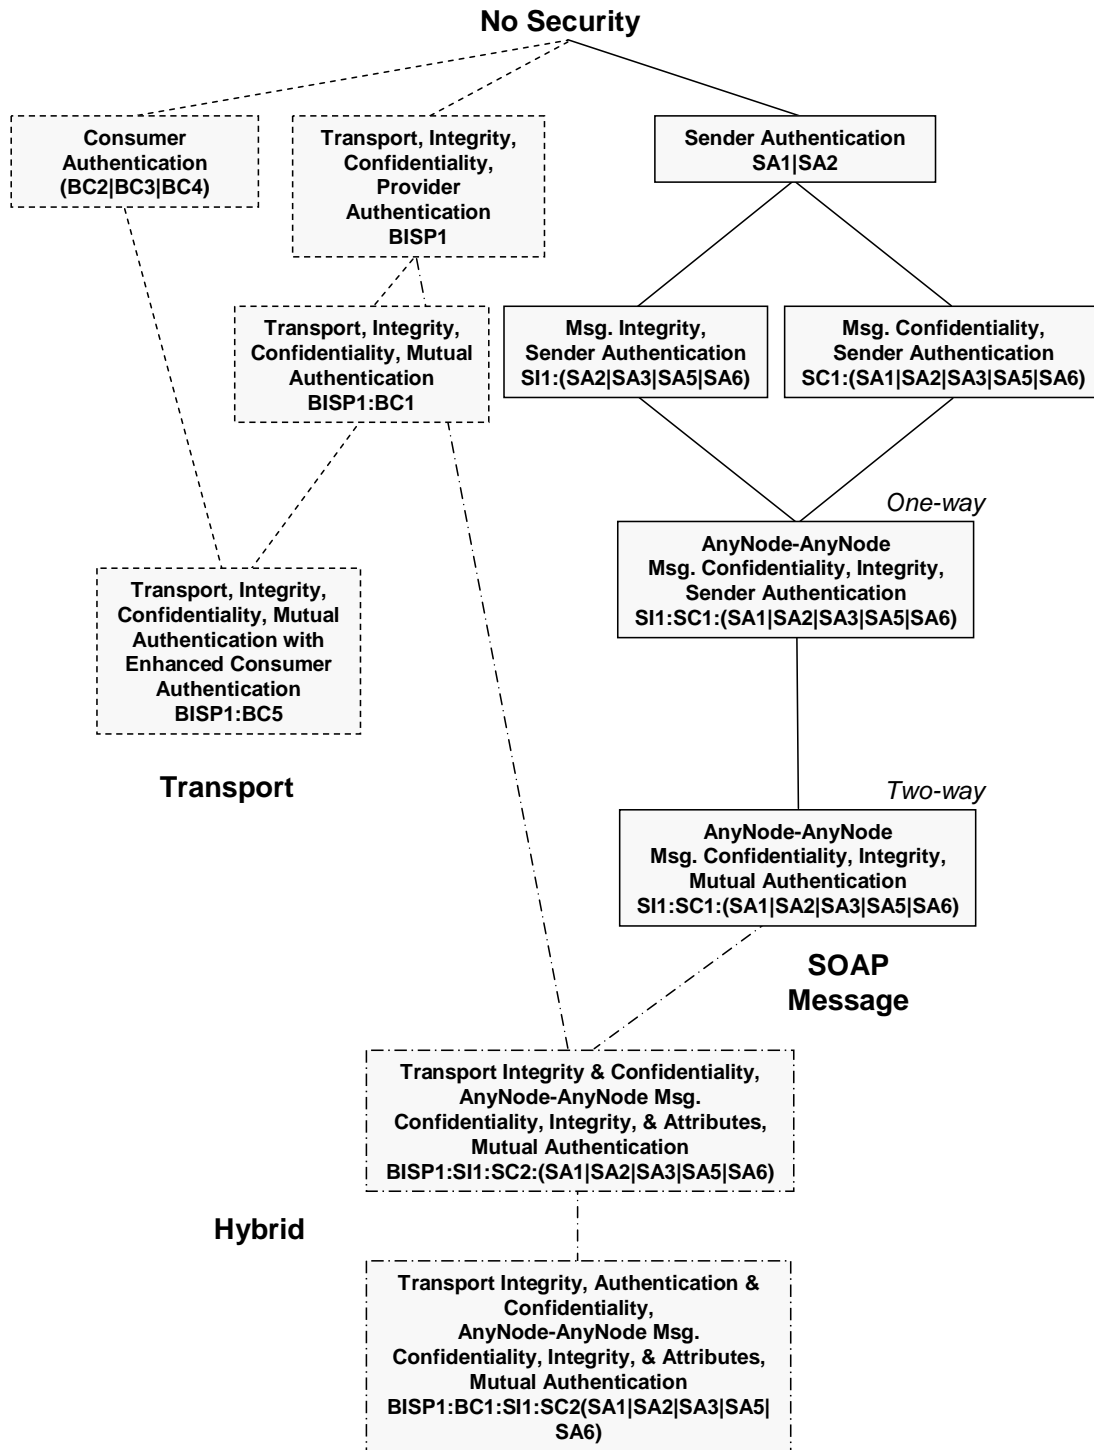

759 There are three basic categories of implementation solutions:

- 760 • transport layer,
- 761 • SOAP message layer
- 762 • hybrid that combines mechanisms from transport and SOAP message layers.

763

764 Figure 1 attempts to depict the potential solution space. It is organized with transport only  
765 mechanism on the left side of the figure and SOAP message mechanisms on the right side.  
766 Hybrid solutions occupy the space in the middle. This figure is not bound to any specific scenario.  
767 Different scenarios may be able to only support a subset of implementations, e.g., one-way  
768 scenario can not support SOAP mutual authentication because there is no SOAP response  
769 message.

770 Additionally, Figure 1 is organized from top to bottom to go from no security to increasing  
771 complex security solutions.

772  
773  
774

Figure 1 Common Security Solutions Hierarchy

775 The eleven solutions identified in Figure 1 are a much smaller set than all possibilities of combined  
 776 security solutions suggested by Table 2 on page 20 and Table 3 on page 25. A basic question is  
 777 what approach or reasoning was used to reduce the numbers? Starting with the four transport  
 778 entries, the two left solutions: BISP1 and BISP1:BC1, are simply SSL/TLS with and without client  
 779 authentication. The BC2 | BC3 | BC4 solution is all that can be done with only using HTTP. The  
 780 last solution is simply the merging/ enhancement of the SSL/TLS solutions and the pure HTTP  
 781 solution. Remember that these two transport level mechanisms: HTTP and SSL/TLS, only work  
 782 between HTTP/TCP level nodes. No SOAP intermediaries are allowed. If multiple HTTP or higher  
 783 nodes are encountered, then multiple instances of the transport layer mechanisms between all  
 784 communication HTTP nodes may need to be used. Additionally, each intermediary has full  
 785 access to all of the data passing by to look at or alter, i.e., no way to insure the integrity or  
 786 confidentiality within the HTTP/TCP intermediaries.

787 Moving to pure SOAP message solutions, the top solution is identification of the sender, without  
 788 integrity or confidentiality. The next two solutions are message level integrity or confidentiality  
 789 along with the identification of who the sender (signer/encryptor) is. The assumption is that  
 790 usually it does not matter if a message is unchanged unless you know who signed (originated)  
 791 the data. Similarly, the secrecy of a message is not important if you can not also insure that  
 792 source of the secret information. The two S1:SC1:(SA1|SA2|SA3|SA5|SA6) solutions utilize all  
 793 the SOAP message level mechanisms: Integrity, Confidentiality and Sender Authentication, for  
 794 one-way and two-way MEP, respectively. Unlike the transport level mechanisms, the SOAP  
 795 message level mechanisms allow integrity, confidentiality and sender authentication of all or part  
 796 of a message to occur between any SOAP nodes, not just the ultimate sender and receiver.

797 Lastly, there is a pair of hybrid cases supported. The first hybrid case uses SSL/TLS to insure the  
 798 confidentiality and integrity of the entire SOAP message data. The usage of SSL/TLS is a simple  
 799 solution that also protects against various types of man-in-the-middle replay attacks that would be  
 800 more complex and expensive to protect against via pure SOAP message level mechanisms. The  
 801 bottom line is that this solution allows stricter security requirements to be imposed between a  
 802 single pair of sender and receiver HTTP/TCP nodes than between other nodes in the message  
 803 exchange. This is just the logical extension that each set of nodes in a complex message  
 804 exchange may have different security requirements. Transport level mechanisms address only  
 805 security requirements between connected HTTP/TCP nodes, while SOAP message level  
 806 mechanisms addresses security requirements between any nodes in a message exchange. Each  
 807 mechanism can be used multiple times for each combination of nodes that has specific security  
 808 needs. The second hybrid case is identical to the first, but adds transport-level, mutual  
 809 authentication of HTTP nodes to the scenario.

## 810 **5.5 Security Considerations for Combinations**

811 In this section we provide an overview of the issues to consider when deploying the combinations  
 812 of transport and message layer security mechanisms defined in Section 5.4. For each of the  
 813 common security solutions previously shown in Figure 1, we summarize the properties of the  
 814 solution, threats addressed, and limitations.

815 These considerations may be used as a guide to select an appropriate security solution for many  
 816 Web Services application deployments. By matching up a particular application's security  
 817 requirements against the solutions in this list, it should be possible in most cases to select an  
 818 optimal combination of transport and/or message layer security mechanisms for that application.

### 819 **5.5.1 Transport Layer Security Solutions**

820 The solutions in this subsection are based solely on transport layer security mechanisms.

821 **5.5.1.1 Consumer Authentication – BC2|BC3|BC4**

822 This solution has the following properties:

- 823 • Provides authentication of the initial SOAP sender (or prior Intermediary) HTTP Node
- 824 to the ultimate SOAP receiver (or latter Intermediary) HTTP Node when they are on
- 825 adjacent HTTP Nodes.

826 **5.5.1.1.1 Threats addressed**

827 T-05

828 **5.5.1.1.2 Limitations**

- 829 • Is only appropriate between adjacent HTTP Nodes not from initial Sender to the
- 830 ultimate Receiver when there are intermediaries.
- 831 • Does not provide authentication of the ultimate SOAP receiver (or latter Intermediary)
- 832 HTTP Node to the initial SOAP sender (or prior Intermediary) HTTP Node.
- 833 • Does not provide origin authentication for the SOAP message (only provides
- 834 authentication of the HTTP Node).
- 835 • Does not provide integrity of a SOAP message.
- 836 • Does not provide confidentiality of a SOAP message.
- 837 • Does not provide detection of replay of a SOAP message.
- 838 • Does not address Man in the Middle principal spoofing attacks.

839 **5.5.1.2 Transport Integrity, Confidentiality, Provider Authentication – BISP1**

840 This solution has the following properties:

- 841 • Provides integrity protection for a SOAP message while in transit from HTTP node to
- 842 HTTP node.
- 843 • Provides confidentiality protection for a SOAP message while in transit from HTTP
- 844 node to HTTP node.
- 845 • Provides authentication of the ultimate SOAP receiver (or latter Intermediary) HTTP
- 846 Node to the Initial SOAP sender (or prior Intermediary) HTTP Node when they are on
- 847 adjacent HTTP Nodes.

848 **5.5.1.2.1 Threats addressed**

849 T-01, T-02

850 **5.5.1.2.2 Limitations**

- 851 • Is only appropriate between adjacent HTTP Nodes.
- 852 • Does not provide authentication of the Initial SOAP sender (or prior Intermediary)
- 853 HTTP Node to the ultimate SOAP receiver (or latter Intermediary) HTTP Node.
- 854 • Does not provide origin authentication for the SOAP message (only provides
- 855 authentication of the HTTP Node).
- 856 • Does not provide detection of replay of a SOAP message.

857 **5.5.1.3 Transport Integrity, Confidentiality, Mutual Authentication – BISP1:BC1**

858 This solution has the following properties:

- 859 • Provides integrity protection for a SOAP message while in transit from HTTP node to  
860 HTTP node.
- 861 • Provides confidentiality protection for a SOAP message while in transit from HTTP  
862 node to HTTP node.
- 863 • Provides authentication of the ultimate SOAP receiver (or latter Intermediary) HTTP  
864 Node to the Initial SOAP sender (or prior Intermediary) HTTP Node when they are on  
865 adjacent HTTP Nodes.
- 866 • Provides authentication of the Initial SOAP sender (or prior Intermediary) HTTP Node  
867 to the ultimate SOAP receiver (or latter Intermediary) HTTP Node when they are on  
868 adjacent HTTP Nodes.

869 **5.5.1.3.1 Threats addressed**

870 T-01, T-02, T-03, T-04, T-05, T-06, T-07, T-08

871 **5.5.1.3.2 Limitations**

- 872 • Is only appropriate between adjacent HTTP Nodes.
- 873 • Does not provide origin authentication for the SOAP message (only provides  
874 authentication of the HTTP Node).

875 **5.5.1.4 Transport Integrity, Confidentiality, Mutual Authentication with Enhanced  
876 Consumer Authentication – BISP1:BC5**

877 This solution has the following properties:

- 878 • Provides integrity protection for a SOAP message while in transit from HTTP node to  
879 HTTP node.
- 880 • Provides confidentiality protection for a SOAP message while in transit from HTTP  
881 node to HTTP node.
- 882 • Provides authentication of the ultimate SOAP receiver (or latter Intermediary) HTTP  
883 Node to the Initial SOAP sender (or prior Intermediary) HTTP Node when they are on  
884 adjacent HTTP Nodes.
- 885 • Provides authentication of the Initial SOAP sender (or prior Intermediary) HTTP Node  
886 to the ultimate SOAP receiver (or latter Intermediary) HTTP Node when they are on  
887 adjacent HTTP Nodes.

888 **5.5.1.4.1 Threats addressed**

889 T-01, T-02, T-03, T-05, T-06, T-07, T-08

890 **5.5.1.4.2 Limitations**

- 891 • Is only appropriate between adjacent HTTP Nodes.
- 892 • Does not provide origin authentication for the SOAP message (only provides  
893 authentication of the HTTP Node).
- 894 • Does not address Man in the Middle principal spoofing attacks.

895 **5.5.2 SOAP Message Layer Security Solutions**

896 The solutions in this subsection are based solely on SOAP message layer security mechanisms.

897 **5.5.2.1 Sender Authentication – SA1|SA2**

898 This solution has the following properties:

- 899 • Provides sender authentication of SOAP message.

900 **5.5.2.1.1 Threats addressed**

901 T-05

902 **5.5.2.1.2 Limitations**

- 903 • Does not provide confidentiality of a SOAP message
- 904 • Does not provide integrity of a SOAP message.
- 905 • Does not provide origin authentication of a SOAP message.
- 906 • Does not provide detection of replay of a SOAP message.
- 907 • Does not provide authentication of HTTP nodes.
- 908 • Does not address Man in the Middle principal spoofing attacks.

909 **5.5.2.2 Message Integrity, Sender Authentication – SI1:(SA2|SA3|SA5|SA6)**

910 This solution has the following properties:

- 911 • Provides sender authentication of SOAP message.
- 912 • Provides end-to-end integrity protection for a SOAP message.
- 913 • Provides origin authentication of a SOAP message.

914 **5.5.2.2.1 Threats addressed**

915 T-01, T-05

916 **5.5.2.2.2 Limitations**

- 917 • Does not provide confidentiality of a SOAP message.
- 918 • Does not provide authentication of HTTP Nodes.
- 919 • Does not provide detection of replay of a SOAP message.

920 **5.5.2.3 Message Confidentiality, Sender Authentication – SC1:(SA1|SA2|SA3|SA5|SA6)**

921 This solution has the following properties:

- 922 • Provides end-to-end confidentiality protection for a SOAP message.
- 923 • Provides sender authentication of SOAP message.

924 **5.5.2.3.1 Threats addressed**

925 T-02, T-05

926 **5.5.2.3.2 Limitations**

- 927 • Does not provide integrity of a SOAP message.

- 928           • Does not provide authentication of HTTP Nodes.
- 929           • Does not provide detection of replay of a SOAP message.
- 930   **5.5.2.4 One-Way AnyNode – AnyNode Message Confidentiality, Integrity, Sender**  
 931   **Authentication – SI1:SC1:(SA1|SA2|SA3|SA5|SA6)**
- 932   This solution has the following properties:
- 933           • Provides end-to-end integrity protection for a SOAP message.
- 934           • Provides end-to-end confidentiality protection for a SOAP message.
- 935           • Provides sender authentication of SOAP message.
- 936           • Provides origin authentication of a SOAP message.
- 937   **5.5.2.4.1 Threats addressed**
- 938   T-01, T-02, T-05, T-06
- 939   **5.5.2.4.2 Limitations**
- 940           • Does not provide authentication of HTTP Nodes.
- 941           • Does not provide detection of replay of a SOAP message.
- 942   **5.5.2.5 Two-Way AnyNode – AnyNode Message Confidentiality, Integrity, Mutual**  
 943   **Authentication – SI1:SC1:(SA1|SA2|SA3|SA5|SA6)**
- 944   This solution has the following properties:
- 945           • Provides end-to-end integrity protection for a SOAP message.
- 946           • Provides end-to-end confidentiality protection for a SOAP message.
- 947           • Provides sender authentication (both consumer and provider) of SOAP message.
- 948           • Provides origin authentication of a SOAP message.
- 949   **5.5.2.5.1 Threats addressed**
- 950   T-01, T-02, T-05, T-06
- 951   **5.5.2.5.2 Limitations**
- 952           • Does not provide authentication of HTTP Nodes.
- 953           • Does not provide detection of replay of a SOAP message.
- 954   **5.5.3 Hybrid Security Solutions**
- 955   The solutions in this subsection are based on a combination of transport and SOAP message  
 956   layer security mechanisms.
- 957   **5.5.3.1 Transport Integrity and Confidentiality, AnyNode – AnyNode Message**  
 958   **Confidentiality, Integrity, Mutual Authentication –**  
 959   **BISP1:SI1:SC1:(SA1|SA2|SA3|SA5|SA6)**
- 960   This solution has the following properties:
- 961           • Provides integrity protection for a SOAP message while in transit from HTTP node to  
 962           HTTP node.

- 963 • Provides confidentiality protection for a SOAP message while in transit from HTTP
- 964 node to HTTP node.
- 965 • Provides authentication of the ultimate SOAP receiver (or latter Intermediary) HTTP
- 966 Node to the Initial SOAP sender (or prior Intermediary) HTTP Node when they are on
- 967 adjacent HTTP Nodes.
- 968 • Provides end-to-end integrity protection for a SOAP message.
- 969 • Provides end-to-end confidentiality protection for a SOAP message across HTTP
- 970 nodes.
- 971 • Provides sender authentication (both consumer and provider) of SOAP message.
- 972 • Provides origin authentication of a SOAP message.

973 **5.5.3.1.1 Threats addressed**

974 T-01, T-02, T-03, T-04, T-05, T-06, T-07, T-08

975 **5.5.3.1.2 Limitations**

- 976 • None

977 **5.5.3.2 Transport Integrity and Confidentiality, Mutual Authentication, AnyNode –**  
 978 **AnyNode Message Confidentiality, Integrity, Mutual Authentication –**  
 979 **BISP1:BC1:SI1:SC1:(SA1|SA2|SA3|SA5|SA6)**

980 This solution has the following properties:

- 981 • Provides integrity protection for a SOAP message while in transit from HTTP node to
- 982 HTTP node.
- 983 • Provides confidentiality protection for a SOAP message while in transit from HTTP
- 984 node to HTTP node.
- 985 • Provides authentication of the ultimate SOAP receiver (or latter Intermediary) HTTP
- 986 Node to the Initial SOAP sender (or prior Intermediary) HTTP Node when they are on
- 987 adjacent HTTP Nodes.
- 988 • Provides authentication of the Initial SOAP sender (or prior Intermediary) HTTP Node
- 989 to the ultimate SOAP receiver (or latter Intermediary) HTTP Node when they are on
- 990 adjacent HTTP Nodes.
- 991 • Provides end-to-end integrity protection for a SOAP message.
- 992 • Provides end-to-end confidentiality protection for a SOAP message across HTTP
- 993 nodes.
- 994 • Provides sender authentication (both consumer and provider) of SOAP message.
- 995 • Provides origin authentication of a SOAP message.

996 **5.5.3.2.1 Threats addressed**

997 T-01, T-02, T-03, T-04, T-05, T-06, T-07, T-08

998 **5.5.3.2.2 Limitations**

- 999 • None

## 1000 6 Scenarios

1001 This section contains descriptions of scenarios, security requirements that might be imposed by  
1002 applications using those scenarios and ways to satisfy those requirements (called solutions).

### 1003 6.1 Notation for Describing Scenarios

1004 The content of a scenario and the conventions used to describe them are as follows.

- 1005 • An introductory paragraph in English
- 1006 • SOAP nodes: A list of the SOAP nodes participating in the scenario. These are given  
1007 arbitrary labels. Some of these labels may have been mentioned by name in the  
1008 introductory paragraph. In describing a scenario with intermediaries it is sometimes  
1009 convenient to give a single node two names. When that is done it will be noted with a  
1010 notation such as

1011 
$$N_k = B$$

- 1012 • HTTP Sessions: A list of HTTP sessions that will carry messages. The notation

1013 
$$S: A \rightarrow B$$

1014 Indicates A-HTTP is the HTTP User Agent that initiates session S talking to HTTP  
1015 Service B-HTTP. Sessions might be created during the scenario or might have existed  
1016 before the scenario begins.

- 1017 • SOAP Messages: A SOAP message path that might include intermediaries carries a  
1018 single SOAP message. Note that this means there is no specific content associated with  
1019 a "SOAP Message" The notation

1020 
$$M: A \rightarrow B \rightarrow \dots \rightarrow Z$$

1021 indicates that the scenario includes a SOAP message that travels on the indicated SOAP  
1022 Path. Nodes in this description of a SOAP message are said to be prior to Nodes to  
1023 their right and later than Nodes to their left in the SOAP message path.

- 1024 • Hops: A Hop describes the transmission in an HTTP message of data related to a SOAP  
1025 message. A Hop is not itself a SOAP message because in common usage "SOAP  
1026 message" refers to a more abstract entity that includes all the hops on a SOAP message  
1027 path.  
1028 The notation

1029 
$$H: A \rightarrow B \text{ (Session S, Message M)}$$

1030 indicates that H is an HTTP Message that is sent by A-HTTP to B-HTTP as part of  
1031 transmission of SOAP message M. Nodes A and B are said to be adjacent (on Message  
1032 M). Whether H is an HTTP request or response depends on whether A or B initiated  
1033 HTTP Session S. If it is a response, the Hop to which it is a response will be indicated.

1034 
$$H: A \rightarrow B \text{ (Session S, Message M, Response to R)}$$

1035 The order in which the Hops are listed is the order in which the HTTP messages are sent.

- 1036 • Security Requirements: This section will contain any Security Requirements that are  
1037 specific to this scenario and any modification of generic security requirements (as  
1038 specified in section 6.4) that are required to make them applicable to this scenario.

## 1039 6.2 Conventions for Describing Security Requirements and Solutions

1040 The description of a security requirement contains:

- 1041 • A short title for the requirement
- 1042 • A description of a security related problem that might be solved using the technologies  
1043 within our scope.
- 1044 • A list of threats (from Section 4) that might subvert potential solutions
- 1045 • A list of challenges (from Section 3) that the requirement participates in.
- 1046 • A list of possible mechanisms called “solutions” that can be used to satisfy this  
1047 requirement. Each solution can be qualified by conditions that must be satisfied for the  
1048 solution to be applicable.

## 1049 6.3 Terminology

1050 In describing the scenarios, requirements and solutions, the following phrases are used.

- 1051 • Node N supplies content X: N-HTTP is the HTTP Sender in a Hop whose HTTP Message  
1052 contained some bytes interpreted in the SOAP Layer as X. If content is originally  
1053 supplied on a Hop by SOAP node A, and SOAP Intermediary B then passes it on  
1054 unchanged in a Hop to SOAP node C. That content is still regarded as having been  
1055 supplied by SOAP node A.
- 1056 • N-HTTP initiates an HTTP session: N-HTTP acting as an HTTP User Agent created a  
1057 session by opening a connection to some HTTP Service associated with some other  
1058 SOAP node.
- 1059 • N-HTTP accepts an HTTP session: N-HTTP acting as an HTTP Service accepts an Http  
1060 becomes a participant in an Http session by accepting an Http Request.

## 1061 6.4 Generic Security Requirements

1062 This section contains security requirements that may be imposed by applications that use the  
1063 scenarios. The requirements in this section are generic to all scenarios and might apply to any  
1064 uses of SOAP Messaging.

1065 This section only presents security requirements for which solutions are available within the  
1066 profiled technologies. Other security requirements that might exist must be addressed by  
1067 application level mechanisms.

### 1068 6.4.1 Requirement: Peer Authentication

1069 A SOAP node A must be able to authenticate to any SOAP node B.

1070 Threats: T-04, T-05

1071 Challenges: C-01

1072 Security solutions:

1073 The following solution may be used to provide authentication of A to B when A is prior to B on  
1074 a SOAP message Path.

- 1075 a) SOAP Sender Authentication (Section 5.2.3) of the SOAP message.

1076 The following solutions may only be used to provide authentication of A to B when A-HTTP  
 1077 initiates a session to B-HTTP.

1078 b) HTTPS X.509 Client Authentication (Section 5.1.4.1)

1079 c) HTTP Basic or Digest Authentication with HTTPS Confidentiality (Reference 5.1.4.2)

1080 d) HTTP Basic or Digest Authentication in the Clear (Reference 5.1.4.3)

1081 The following solution may only be used to provide authentication of B to A when A-HTTP  
 1082 initiates a session to B-HTTP.

1083 e) HTTPS X.509 Server Authentication (Section 5.1.4.1)

1084

1085 Solutions (c) and (d) do not address T-04 (man in the middle)

1086 **6.4.2 Requirement: Origin Authentication**

1087 A party A in possession of a party's (B's) public key must be able to prove that signed SOAP  
 1088 message content was produced by party A. And it must be possible to retain that ability as long  
 1089 as the SOAP message is retained.

1090 Threats: T-04, T-05, T(OOS)-13

1091 Challenges: C-01, C-05

1092 Security solution:

1093 a) Digital Signature on Message. SOAP Message Layer Integrity (Section 5.2.1)

1094 **6.4.3 Requirement: Integrity**

1095 A SOAP node B must be able to detect alteration of content supplied by a SOAP node A

1096 Threats: T-01

1097 Challenges: C-03

1098 Security solution:

1099 The following solution may be used to provide integrity for any content supplied by SOAP  
 1100 node A.

1101 a) SOAP Layer Integrity (Section 5.2.1)

1102 The following solution may be used to provide integrity for any content while it is in transit on  
 1103 a Hop to or from A.

1104 b) Transport Layer Integrity (Section 5.1.1)

1105

1106 **6.4.4 Requirement: Confidentiality**

1107 A SOAP node B must be able to exclusively access confidential content supplied by a SOAP  
 1108 node A and intended for SOAP node B.

1109 Threats: T-02

1110 Challenges: C-04

1111 Security solution:

1112 The following solution may be used to provide confidentiality of any content supplied by Node  
1113 A

1114 a) SOAP Layer Confidentiality (Section 5.2.2)

1115 The following solution may be used to provide confidentiality for content while in transit from  
1116 A-HTTP to B-HTTP

1117 b) Transport Layer Confidentiality (Section 5.1.2)

#### 1118 **6.4.5 Requirement: Message Uniqueness**

1119 A SOAP node B must be able to detect that a previous received message or part of a previous  
1120 message from SOAP node A has been replayed.

1121 Threats: T-07, T-08, T-09

1122 Challenges: C-05

1123 Security solution:

1124 The following solution may be used to provide replay protection for any content received by  
1125 SOAP node

1126 a) Transport Layer Integrity (Section 5.1.1). Currently, there is no application interoperability  
1127 solution at the SOAP message layer.

## 1128 **6.5 Scenario Descriptions**

### 1129 **6.5.1 Scenario: One-Way**

1130 A SOAP message is sent over a SOAP message path from a SOAP node  $N_0$  through zero or  
1131 more SOAP Intermediaries to a SOAP node  $N_k$  using a series of HTTP Requests.

1132 This scenario applies to situations where the loss of individual SOAP messages is insignificant  
1133 (for example, in a status monitoring scenario where periodic status update events are provided  
1134 such that if one update event is lost, a subsequent update event will convey correct status). No  
1135 SOAP message response is generated by  $N_k$  or expected by  $N_0$ . Regardless of the protocol  
1136 implemented by the transport layer,  $N_0$  receives no SOAP message response.

1137 The transport layer may not guarantee delivery of the SOAP message. The  $N_0$  or any SOAP  
1138 Intermediary may not be aware whether a SOAP message was successfully sent or delivered to,  
1139 received or processed by, any other node. Receipt of an HTTP Response indicates that at the  
1140 very least that the HTTP Node associated with the receiver has received the HTTP Request but  
1141 does not guarantee that the SOAP message will ever arrive at the receiver.

1142 SOAP Nodes:

- 1143 •  $N_0$
- 1144 • [OPTIONAL]  $N_1, N_2, \dots, N_{k-1}$  (SOAP Intermediaries)
- 1145 •  $N_k$

1146 HTTP Sessions:

- 1147 • (for  $r=1, \dots, k-1$ )  $S_r : N_r \rightarrow N_{r+1}$

1148 SOAP Messages:

1149       • M:  $N_0 \rightarrow \dots \rightarrow N_k$

1150 Hops:

1151       • (for  $r = 1, \dots, k-1$ )  $H_r: N_r \rightarrow N_{r+1}$  (Session  $S_r$ )

1152 Security Requirements

1153       None beyond generic requirements of Section 6.4

### 1154 **6.5.2 Scenario: Synchronous Request/Response**

1155 This scenario is derived from the Synchronous Request/Response scenario in the WS-I Basic  
1156 Applications Usage Scenarios [BPSA UsageScenarios]

1157 A SOAP message (called the request) is sent from a SOAP node  $N_0$  through zero or more SOAP  
1158 Intermediaries to a SOAP node  $N_k$ . A SOAP message called the response is sent by  $N_k$  to  $N_0$ .  
1159 The SOAP Path of this SOAP message is the reverse of that of the request. The Hops used in  
1160 the transmission of the response are the HTTP responses to the Hops used in the transmission of  
1161 the request.

1162 SOAP Nodes:

1163       •  $N_0$

1164       • [OPTIONAL]  $N_1, N_2, \dots, N_{k-1}$  (SOAP Intermediaries)

1165       •  $N_k$

1166 Sessions:

1167       • (for  $r = 0, \dots, k-1$ )  $S_0: N_0 \rightarrow N_1$

1168 SOAP Messages:

1169       • REQUEST:  $N_0 \rightarrow N_1 \rightarrow \dots \rightarrow N_k$

1170       • RESPONSE:  $N_k \rightarrow N_{k-1} \rightarrow \dots \rightarrow N_0$

1171 Hops:

1172       • (for  $r = 0, \dots, k-1$ )  $H\text{-REQ}_r: N_r \rightarrow N_{r+1}$  (Session  $S_r$ , Message REQUEST)

1173       • (for  $r = k, \dots, 1$ )  $H\text{-RESP}_r: N_r \rightarrow N_{r-1}$  (Session  $S_{r-1}$ , Message RESPONSE, response  
1174 to  $H\text{-REQ}_{r-1}$ )

1175 Security Requirements

1176       None beyond generic requirements of Section 6.4

### 1177 **6.5.3 Basic Callback**

1178 This scenario was derived from the Basic call back scenario in the WS-I Basic Sample  
1179 Applications Usage Scenarios. [BPSA UsageScenarios]

1180 The first SOAP Message APPLICATION-REQUEST is sent from Node A through zero or more to  
1181 Node B through a series of Hops. APPLICATION-REQUEST contains information that indicates  
1182 where B should send the APPLICATION-RESPONSE.

- 1183 B sends a SOAP Message (acknowledgement) to A through the Http responses of the same set  
 1184 of Hops
- 1185 After APPLICATION REQUEST is processed B sends a SOAP Message APPLICATION-  
 1186 RESPONSE to A through zero or more intermediaries through a series of Hops.
- 1187 A sends a SOAP Message (acknowledgement) to B through the HTTP response across the same  
 1188 set of Hops.
- 1189 The APPLICATION-REQUEST and APPLICATION RESPONSE are related via correlation  
 1190 information that is provided by A in APPLICATION-REQUEST and duplicated by B into  
 1191 APPLICATION-RESPONSE.
- 1192 SOAP Nodes:
- 1193 •  $A = AP-REQ_0 = AP-RESP_1$
  - 1194 •  $B = AP-REQ_k = AP-RESP_0$
  - 1195 • [OPTIONAL]  $AP-REQ_1, AP-REQ_2, \dots AP-REQ_{k-1}$  (SOAP Intermediaries)
  - 1196 • [OPTIONAL]  $AP-RESP_1, AP-RESP_2, \dots AP-RESP_{l-1}$  (SOAP Intermediaries)
- 1197 Sessions:
- 1198 • (for  $r = 0, \dots, k-1$ )  $REQ-SESSION_r: AP-REQ_r \rightarrow AP-REQ_{r+1}$
  - 1199 • (for  $r = 0, \dots, l-1$ )  $RESP-SESSION_r: AP-RESP_r \rightarrow AP-RESP_{r+1}$
- 1200 SOAP Messages:
- 1201 • APPLICATION REQUEST:  $A \rightarrow AP-REQ_1 \rightarrow \dots \rightarrow AP-REQ_{k-1} \rightarrow B$
  - 1202 • ACK-1:  $B \rightarrow AP-REQ_1 \rightarrow \dots \rightarrow AP-REQ_l \rightarrow A$
  - 1203 • APPLICATION RESPONSE:  $B \rightarrow AP-RESP_1 \rightarrow \dots \rightarrow AP-RESP_{l-1} \rightarrow A$
  - 1204 • ACK-2:  $A \rightarrow AP-RESP_1 \rightarrow \dots \rightarrow AP-RESP_l \rightarrow B$
- 1205 Hops:
- 1206 • (for  $r = 0, \dots, k-1$ )  $REQ-HOP_r: AP-REQ_r \rightarrow AP-REQ_{r+1}$   
 1207 (Session  $AP-REQ_r$ , Message APPLICATION REQUEST)
  - 1208 • (for  $r = k-1, \dots, 0$ )  $ACK-1-HOP_r: AP-REQ_{r+1} \rightarrow AP-REQ_r$   
 1209 (Session  $AP-REQ_r$ , Message ACK-1, Http response)
  - 1210 • (for  $r = 0, \dots, l-1$ )  $RESP-HOP_r: AP-RESP_r \rightarrow AP-RESP_{r+1}$   
 1211 (Session  $AP-RESP_r$ , Message APPLICATION RESPONSE)
  - 1212 • (for  $r = l-1, \dots, 0$ )  $ACK-2-HOP_r: AP-RESP_{r+1} \rightarrow AP-RESP_r$   
 1213 (Session  $AP-RESP_r$ , Message ACK-2, Http response)
- 1214 Security Requirements:
- 1215 Requirement: Message Correlation
- 1216 SOAP Node A must be able to securely determine whether content of hop  $AP-RESP_{r+1}$  supplied  
 1217 by SOAP Node B was generated in response to APPLICATION-REQUEST. This requirement  
 1218 addresses the fact that related messages may be delivered on unrelated sessions.
- 1219 Threats: T-01, T-02, T-03, T-04, T-05, T-08, T-09

- 1220 Challenges: C-01, C-02, C-03, C-04
- 1221 Security solutions:
- 1222 Providing a solution for this requirement would require composition of a solution using techniques  
1223 that are not described in the documents that are in scope for this profile.
- 1224 An example of a solution would be for SOAP Node A to provide (with confidentiality, integrity and  
1225 authentication) some correlation information X along with the content C. SOAP Node B would  
1226 provide (with confidentiality, integrity and authentication) the same correlation information X along  
1227 with the application level response.
- 1228 Requirement: Node Correlation
- 1229 SOAP Node A must be able to securely determine whether the content of AP-RESP<sub>r+1</sub> was  
1230 supplied by SOAP Node B in response to content C sent to SOAP Node B.
- 1231 This requirement addresses the possibility that the credential Q used by SOAP Node A to identify  
1232 SOAP Node B when targeting content to SOAP Node B is not the same credential R used by  
1233 SOAP Node B to identify itself when targeting content to SOAP Node A.
- 1234 Threats: T-01, T-02, T-03, T-04, T-05, T-08, T-09
- 1235 Challenges: C-01, C-02, C-03, C-04
- 1236 Security solution:
- 1237 Providing a solution for this requirement would require composition of a solution using techniques  
1238 that are not described in the documents that are in scope for this profile.
- 1239 The simplest example of a solution, based on the example given for Message Correlation, would  
1240 be to ensure that the same credential was used to provide confidentiality to, and authentication  
1241 from, SOAP Node B (Q = R). A more complex solution, still based on the Message Correlation  
1242 example, would require SOAP Node A to have access to some mapping of several credentials to  
1243 SOAP Node B (Q => B and R => B).

1244 **7 Out of Scope**

1245 This section contains discussions of security aspects that are not considered in the security  
 1246 requirements of the scenarios. It is included so that the reader is aware that these have not been  
 1247 overlooked. The primary reasons that they are not considered is that mechanisms to deal with  
 1248 them are not present within the technologies in the charter of this working group or because in  
 1249 some cases (e.g. Credentials Issuance) the solutions are not technological.

1250 **7.1 Security Challenges**

1251 **7.1.1 C-05: Non-Repudiation**

1252 **Definition:** Non-repudiation: A security service that provides protection against false denial of  
 1253 involvement in a communication.

1254 **Explanation:** Protection against false denial of an action associated with a Web service  
 1255 message. Non-repudiation technologies do not prevent repudiation, but rather provide evidence  
 1256 that may be used by a third party to resolve disputes.

1257 **Threat association:** Accountability related threats along with threats associated with C-01, C-02  
 1258 and C-03 must be addressed relative to this challenge and needs to be discussed further.

1259 **7.1.2 C-06: Credentials Issuance**

1260 **Definition:** Credential(s): Data that is transferred or presented to establish either a claimed  
 1261 identity or the authorizations of a system entity.

1262 **Explanation:** The process of initially providing a principal with a means of identifying itself, via  
 1263 online or offline mechanisms. Traditionally, “issuance” refers only to certificates, but here it is  
 1264 used for any information furnished by an authority that is willing to vouch for the principal. We  
 1265 believe that this security challenge is out of scope.

1266 Creation of a credential via transformation from an existing credential to an equivalent one in  
 1267 another format is not issuance in the sense of this section.

1268 **Threat association:** Out of scope

1269 **7.2 Threats**

1270 The following threats are considered out of scope for Basic Security Profile. However, these are  
 1271 real threats that need to be considered in any secure application or architecture. There are well-  
 1272 known approaches to addressing these threats that are not documented here.

1273 Note that out of scope threats are designated as T(OOS)-XX.

1274

| ID | Name | Description |

|----|------|-------------|

| ID        | Name                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| T(OOS)-01 | Key Attack / Weak Algorithm | <p>The algorithm chosen is subject to attacks and/or the key(s) can be compromised. This covers a variety of attacks. Most of these have to do with details of the implementation or operational procedures, which is the reason for considering them to be outside the scope of a specification profile. However some aspects of profiles, e.g. selection of cryptographic algorithms, would be relevant to this threat. Here as elsewhere there are two levels: some parameter settings would be universally considered insecure, e.g. null encryption algorithm. In other cases, the choice would be a matter of local policy. For example, some organizations consider a 1024 bit RSA key adequately strong and others do not. Still others consider it satisfactory for some uses and not others.</p> |
| T(OOS)-02 | Traffic Analysis            | <p>By analyzing aspects of the messages such as its source, destination, size, frequency, etc., determinations can be made about potential contents (e.g. it is determined that one company may be trying to buy another). This has many subtle forms. For example, during WW II, Russian scientists deduced that the Americans were building an Atomic Bomb, because the physicists in question had stopped publishing papers.</p>                                                                                                                                                                                                                                                                                                                                                                        |
| T(OOS)-03 | Host Penetration/Access     | <p>Information is obtained by compromising a computer system (e.g. unauthorized access to a computer). Any threat analysis must assume some part of the system is secure. This is called the Trusted Computing Base (TCB). If there is no TCB, it is not possible to conclude anything about the behavior of the system, since presumably an attacker could modify its behavior at will. Thus, in a sense, this threat is out of scope of ANY design or specification, although certainly not out of scope of implementation and operations.</p>                                                                                                                                                                                                                                                           |
| T(OOS)-04 | Network Penetration/Access  | <p>Information is obtained by compromising a computer network (e.g. unauthorized access to an internal network). This threat presumes a topological approach to security, e.g. firewalls or security gateways. If appropriately strong mechanisms are used on an end-to-end basis, network attacks are reduced to denial-of-service. Thus this threat is out of scope because it is essentially equivalent to the standard assumption of an untrusted network.</p>                                                                                                                                                                                                                                                                                                                                         |
| T(OOS)-05 | Timing                      | <p>By analyzing the time it takes to perform an action, information can be deduced (e.g. validity of a username, or key information). This is out of scope because it is an implementation issue rather than a specification issue. However, it should be noted that some published cryptographic timing attacks require timing measurements which are much smaller than the average variability of latency in typical networks and thus not of practical concern.</p>                                                                                                                                                                                                                                                                                                                                     |

| ID        | Name             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| T(OOS)-06 | Covert Channels  | Information is conveyed outside of a secure perimeter by means of secret communication paths (e.g. by toggling an externally visible flag, secret information is conveyed). This threat is usually only considered seriously in military or intelligence environments. Typically the engineering approach taken is not to eliminate the channel, but to reduce its bandwidth to the point of being useless.                                                                                                                                                                                                                                                                 |
| T(OOS)-07 | Message Archives | By penetrating the queue of a store-and-forward SOAP intermediary, or the store of an archival system, information about a message can be discovered (e.g. a message in a store and forward queue can be discovered which otherwise wouldn't have been seen). Note that in many circumstances this is a variation on T(OOS)-03. The main reason for calling out this threat separately is because end-to-end message protection measures can counter it, whereas hop-by-hop measures cannot.                                                                                                                                                                                |
| T(OOS)-08 | Network Spoofing | A message is sent which appears to be from another machine (e.g. BadGuy sends a message which appears as though it is from GoodGuy). Comments similar to those under T(OOS)-04 apply here. If the message does not reach the application, there is little a profile of a specification can have to say about it. If it does reach the application, it is essentially the same as T-03 and T-05.                                                                                                                                                                                                                                                                             |
| T(OOS)-08 | Trojan Horse     | Information is secretly passed along with the message that plants a Trojan horse (e.g. a message is added which is detected by planted software which causes special behaviors to occur).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| T(OOS)-09 | Virus            | Information is secretly passed along with the message that plants a virus (e.g. a message is added which is detected by planted software which causes special behaviors to occur). Note that this is a variation on T-08. Viruses are usually planted by action of unsuspecting user or occasionally program flaw that triggers execution without user action. This can be contrasted with a Worm, which spreads itself autonomously without user action. Worms typically execute other threats found in this table in automated fashion. Some authorities have abandoned the distinction among various programmatic threats and use the term "malware" to cover all types. |
| T(OOS)-10 | Tunneling        | Information is secretly passed along with the message (e.g. a message is added which is detected by planted software which causes special behaviors to occur). Note that this is a variation on T-01.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| ID        | Name                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| T(OOS)-11 | Denial of Service        | Silver Bullet: specific messages or command sequences causes failure. Almost invariably a result of implementation error, not design error. (Note that this can also result in a system or application compromise instead of merely a Denial of Service.) Addressing this threat is outside of the scope of a profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| T(OOS)-12 | Denial of Service        | <p>Flooding: Sheer volume of message traffic overloads some critical resource, typically server or network link bandwidth. This is usually a configuration issue not a design issue. If the bogus traffic is truly indistinguishable from legitimate traffic there may be no defense. It is important to try to</p> <ul style="list-style-type: none"> <li>• detect that an attack is occurring</li> <li>• determine the true source.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| T(OOS)-13 | Repudiation              | <p>A message is sent and then the sender denies having sent it. Achieving non-repudiation requires both technical and business aspects since a party may always claim a disconnect with the technology ("the software did it, not me, I didn't know"). Public Key cryptographic systems have a special property that cannot be achieved by secret key systems without the use of a trusted third party. The property is that it is possible for a party to be able to verify something e.g. a digital signature, without being able to produce it themselves. When this technical property was first observed, it was called "non-repudiation". Much later it became widely believed that non-repudiation was a well-established legal concept (It is not.) and very desirable for electronic commerce. The confusion between the technical and legal meanings of this term continues.</p> |
| T(OOS)-14 | Incorrect implementation | <p>If an error is made in implementation of the security protecting a Web service, an attacker could compromise the service by exploiting this security weakness. For example, a signed SOAP message might be susceptible to a certificate substitution attack, which would allow an attacker to modify a message or attach incorrect claims to it. Such threats are out of scope of the profile, as is explicit description of best practices to avoid potential security pitfalls.</p>                                                                                                                                                                                                                                                                                                                                                                                                   |

| ID        | Name                         | Description                                                                                                                                                                                                                                                                                                                                                      |
|-----------|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| T(OOS)-15 | Poorly designed Web services | Simply securing Web services does not secure an application as a whole. A poorly designed service, such as one that is susceptible to SQL injection attacks, or spawns a shell that accepts parameters from a SOAP message, can be compromised even though the transaction itself is considered secure. Such threats are naturally out of scope of this profile. |

1275

**Table 4: Out of Scope Threats**

**1276 8 Acronyms**

- 1277 HTTP – Hypertext Transfer Protocol
- 1278 HTTPS – Hypertext Transfer Protocol Secure
- 1279 IETF – Internet Engineering Task Force
- 1280 MD5 – one Message-Digest algorithm (RFC-1321)
- 1281 MEP – Message Exchange Pattern
- 1282 MIME – Multipurpose Internet Mail Extensions
- 1283 OASIS – not an acronym
- 1284 OOS – Out Of Scope
- 1285 REL – Rights Expression Language
- 1286 RFC – Request for Comment (Used by IETF)
- 1287 SAML – Security Assertions Markup Language
- 1288 SCM – Supply Chain Management; the WS-I Sample Application for 1.0
- 1289 SHA – Secure Hash Algorithm
- 1290 SOAP - Simple Object Access Protocol
- 1291 SSL – Secure Sockets Layer
- 1292 TLS – Transport Layer Security
- 1293 WS-Security – OASIS SOAP Message Security specifications
- 1294 XML – Extensible Markup Language
- 1295 X.509 – An ITU (International Telecommunication Union) standard for “certificates” Also known as
- 1296 ISO/IEC 9594-8:1988
